

The Molecules of Life

- All living things are made up of four classes of large biological molecules: carbohydrates, lipids, proteins, and nucleic acids
 - **Macromolecules** are large molecules and are complex
 - Large biological molecules have unique properties that arise from the orderly arrangement of their atoms
- © 2018 Pearson Education Ltd.

Figure 5.1

Figure 5.1a

The scientist in the foreground is using 3-D glasses to help her visualize the structure of the protein displayed on her screen.

Concept 5.1: Macromolecules are polymers, built from monomers

- A **polymer** is a long molecule consisting of many similar building blocks
 - The repeating units that serve as building blocks are called **monomers**
 - Carbohydrates, proteins, and nucleic acids are polymers
- © 2018 Pearson Education Ltd.

The Synthesis and Breakdown of Polymers

- **Enzymes** are specialized macromolecules that speed up chemical reactions such as those that make or break down polymers
 - A **dehydration reaction** occurs when two monomers bond together through the loss of a water molecule
 - Polymers are disassembled to monomers by **hydrolysis**, a reaction that is essentially the reverse of the dehydration reaction
- © 2018 Pearson Education Ltd.

The Diversity of Polymers

- A cell has thousands of different macromolecules
- Macromolecules vary among cells of an organism, vary more within a species, and vary even more between species
- A huge variety of polymers can be built from a small set of monomers

© 2018 Pearson Education Ltd.

Concept 5.2: Carbohydrates serve as fuel and building material

- **Carbohydrates** include sugars and the polymers of sugars
- The simplest carbohydrates are monosaccharides, or simple sugars
- Carbohydrate macromolecules are polysaccharides, polymers composed of many sugar building blocks

© 2018 Pearson Education Ltd.

Sugars

- **Monosaccharides** have molecular formulas that are usually multiples of CH_2O
- Glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) is the most common monosaccharide
- Monosaccharides are classified by
 - The location of the carbonyl group (as aldose or ketose)
 - The number of carbons in the carbon skeleton

© 2018 Pearson Education Ltd.

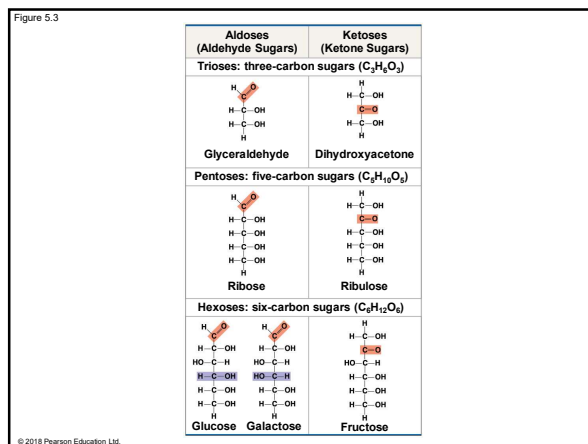

Figure 5.3a

Figure 5.3c

© 2018 Pearson Education, Ltd.

- Though often drawn as linear skeletons, in aqueous solutions many sugars form rings
- Monosaccharides serve as a major fuel for cells and as raw material for building molecules

(b) Abbreviated ring structure

© 2018 Pearson Education, Ltd.

- A **disaccharide** is formed when a dehydration reaction joins two monosaccharides
- This covalent bond is called a **glycosidic linkage**

© 2018 Pearson Education, Ltd.

Polysaccharides

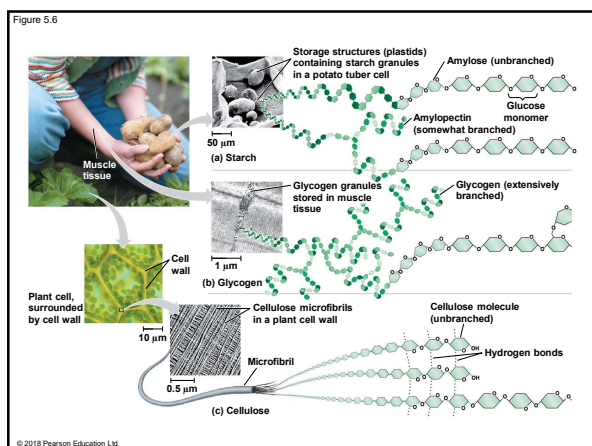

- **Polysaccharides**, the polymers of sugars, have storage and structural roles
- The architecture and function of a polysaccharide are determined by its sugar monomers and the positions of its glycosidic linkages

© 2018 Pearson Education Ltd.

Storage Polysaccharides

- **Starch**, a storage polysaccharide of plants, consists of glucose monomers
- Plants store surplus starch as granules within chloroplasts and other plastids
- The simplest form of starch is amylose

© 2018 Pearson Education Ltd.

Animation: Polysaccharides

© 2018 Pearson Education Ltd.

- **Glycogen** is a storage polysaccharide in animals
- Glycogen is stored mainly in liver and muscle cells
- Hydrolysis of glycogen in these cells releases glucose when the demand for sugar increases

© 2018 Pearson Education Ltd.

Structural Polysaccharides

- The polysaccharide **cellulose** is a major component of the tough wall of plant cells
- Like starch, cellulose is a polymer of glucose, but the glycosidic linkages differ
- The difference is based on two ring forms for glucose: alpha (α) and beta (β)

© 2018 Pearson Education Ltd.

Figure 5.7

(a) α and β glucose ring structures

(b) Starch: 1-4 linkage of α glucose monomers

(c) Cellulose: 1-4 linkage of β glucose monomers

© 2018 Pearson Education Ltd.

Figure 5.7a

(a) α and β glucose ring structures

© 2018 Pearson Education Ltd.

Figure 5.7b

(b) Starch: 1-4 linkage of α glucose monomers

(c) Cellulose: 1-4 linkage of β glucose monomers

© 2018 Pearson Education Ltd.

- Starch (α configuration) is largely helical
- Cellulose molecules (β configuration) are straight and unbranched
- Some hydroxyl groups on the monomers of cellulose can hydrogen-bond with hydroxyls of parallel cellulose molecules

© 2018 Pearson Education Ltd.

- Enzymes that digest starch by hydrolyzing α linkages can't hydrolyze β linkages in cellulose
- The cellulose in human food passes through the digestive tract as "insoluble fiber"
- Some microbes use enzymes to digest cellulose
- Many herbivores, from cows to termites, have symbiotic relationships with these microbes

© 2018 Pearson Education Ltd.

- **Chitin**, another structural polysaccharide, is found in the exoskeleton of arthropods
- Chitin also provides structural support for the cell walls of many fungi

© 2018 Pearson Education Ltd.

Figure 5.8

© 2018 Pearson Education Ltd.

Figure 5.8a

© 2018 Pearson Education Ltd.

Concept 5.3: Lipids are a diverse group of hydrophobic molecules

- **Lipids** are the one class of large biological molecules that does not include true polymers
- The unifying feature of lipids is that they mix poorly, if at all, with water
- Lipids consist mostly of hydrocarbon regions
- The most biologically important lipids are fats, phospholipids, and steroids

© 2018 Pearson Education Ltd.

Fats

- **Fats** are constructed from two types of smaller molecules: glycerol and fatty acids
- Glycerol is a three-carbon alcohol with a hydroxyl group attached to each carbon
- A **fatty acid** consists of a carboxyl group attached to a long carbon skeleton

© 2018 Pearson Education Ltd.

Animation: Fats

- Fats separate from water because water molecules hydrogen-bond to each other and exclude the fats
 - In a fat, three fatty acids are joined to glycerol by an ester linkage, creating a **triacylglycerol**, or triglyceride
 - The fatty acids in a fat can be all the same or of two or three different kinds
- © 2018 Pearson Education Ltd.

- Fats made from saturated fatty acids are called saturated fats and are solid at room temperature
- Most animal fats are saturated
- Fats made from unsaturated fatty acids are called unsaturated fats or oils and are liquid at room temperature
- Plant fats and fish fats are usually unsaturated

© 2018 Pearson Education, Ltd.

- A diet rich in saturated fats may contribute to cardiovascular disease through plaque deposits
- Hydrogenation is the process of converting unsaturated fats to saturated fats by adding hydrogen
- Hydrogenating vegetable oils also creates unsaturated fats with *trans* double bonds
- These ***trans* fats** may contribute more than saturated fats to cardiovascular disease

© 2018 Pearson Education, Ltd.

- The major function of fats is energy storage
- Humans and other mammals store their long-term food reserves in adipose cells
- Adipose tissue also cushions vital organs and insulates the body

© 2018 Pearson Education, Ltd.

Phospholipids

- In a **phospholipid**, two fatty acids and a phosphate group are attached to glycerol
- The two fatty acid tails are hydrophobic, but the phosphate group and its attachments form a hydrophilic head

© 2018 Pearson Education, Ltd.

- When phospholipids are added to water, they self-assemble into double-layered sheets called bilayers
 - At the surface of a cell, phospholipids are also arranged in a bilayer, with the hydrophobic tails pointing toward the interior
 - The phospholipid bilayer forms a boundary between the cell and its external environment
- © 2018 Pearson Education Ltd.

Steroids

- **Steroids** are lipids characterized by a carbon skeleton consisting of four fused rings
 - **Cholesterol**, a type of steroid, is a component in animal cell membranes and a precursor from which other steroids are synthesized
 - A high level of cholesterol in the blood may contribute to cardiovascular disease
- © 2018 Pearson Education Ltd.

Video: Space-filling Model of Cholesterol

Video: Stick Model of Cholesterol

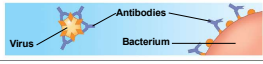

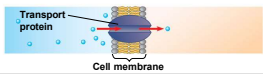

Concept 5.4: Proteins include a diversity of structures, resulting in a wide range of functions

- Proteins account for more than 50% of the dry mass of most cells
- Some proteins speed up chemical reactions
- Other protein functions include defense, storage, transport, cellular communication, movement, and structural support

© 2018 Pearson Education Ltd.

Figure 5.13b

Hormonal proteins

Function: Coordination of an organism's activities
Example: Insulin, a hormone secreted by the pancreas, causes other tissues to take up glucose, thus regulating blood sugar concentration.

Receptor proteins

Function: Response of cell to chemical stimuli
Example: Receptors built into the membrane of a nerve cell detect signaling molecules released by other nerve cells.

Contractile and motor proteins

Function: Movement
Examples: Motor proteins are responsible for the undulations of cilia and flagella. Actin and myosin proteins are responsible for the contraction of muscles.

Structural proteins

Function: Support
Examples: Keratin is the protein of hair, horns, feathers, and other skin appendages. Insects and spiders use silk fibers to make their cocoons and webs, respectively. Collagen and elastin proteins provide a fibrous framework in animal connective tissues.

© 2018 Pearson Education Ltd.

- Enzymes are proteins that act as **catalysts** to speed up chemical reactions
- Enzymes can perform their functions repeatedly, functioning as workhorses that carry out the processes of life

© 2018 Pearson Education, Ltd.

- Proteins are all constructed from the same set of 20 amino acids
- Polypeptides** are unbranched polymers built from these amino acids
- A **protein** is a biologically functional molecule that consists of one or more polypeptides

© 2018 Pearson Education, Ltd.

Amino Acid Monomers

- Amino acids** are organic molecules with amino and carboxyl groups
- Amino acids differ in their properties due to differing side chains, called R groups

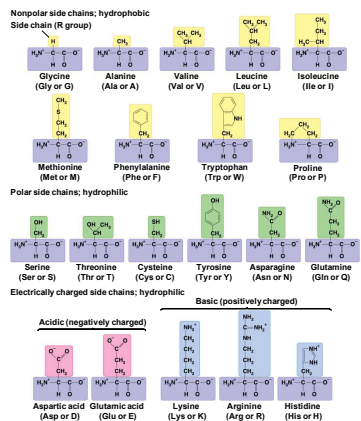

© 2018 Pearson Education, Ltd.

Figure 5.UN01

© 2018 Pearson Education, Ltd.

Figure 5.14

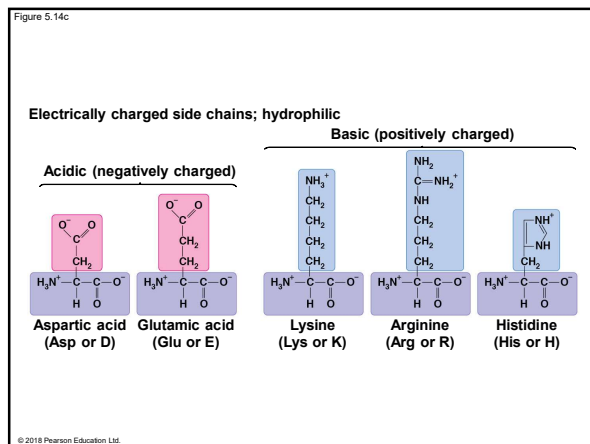

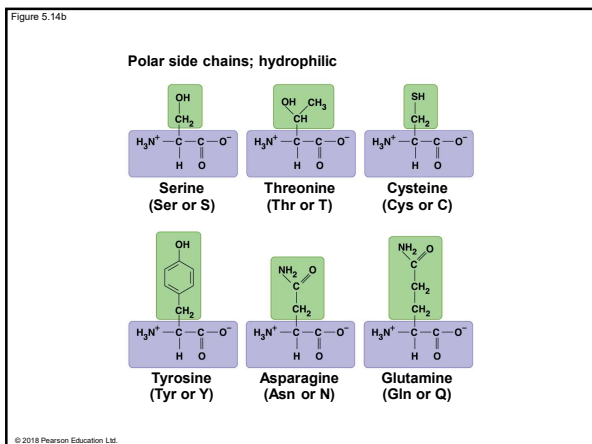

© 2018 Pearson Education, Ltd.

Figure 5.14a

Polypeptides (Amino Acid Polymers)

- Amino acids are linked by covalent bonds called **peptide bonds**
- A polypeptide is a polymer of amino acids
- Polypeptides range in length from a few to more than 1,000 monomers
- Each polypeptide has a unique linear sequence of amino acids, with a carboxyl end (C-terminus) and an amino end (N-terminus)

© 2018 Pearson Education, Ltd.

Protein Structure and Function

- The specific activities of proteins result from their intricate three-dimensional architecture
- A functional protein consists of one or more polypeptides precisely twisted, folded, and coiled into a unique shape

© 2018 Pearson Education, Ltd.

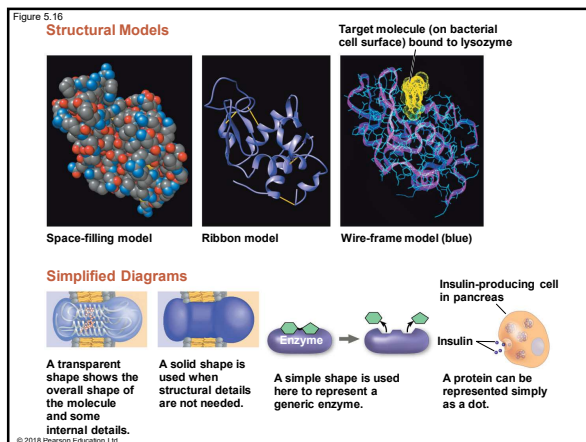

Figure 5.16a

Figure 5.16b

Animation: Protein Structure Introduction

© 2018 Pearson Education, Ltd.

- The sequence of amino acids determines a protein's three-dimensional structure
- A protein's structure determines how it works
- The function of a protein usually depends on its ability to recognize and bind to some other molecule

© 2018 Pearson Education, Ltd.

Figure 5.17

© 2018 Pearson Education Ltd.

Four Levels of Protein Structure

- The primary structure of a protein is its unique sequence of amino acids
- Secondary structure, found in most proteins, consists of coils and folds in the polypeptide chain
- Tertiary structure is determined by interactions among various side chains (R groups)
- Quaternary structure results when a protein consists of multiple polypeptide chains

© 2018 Pearson Education Ltd.

Figure 5.18a

© 2018 Pearson Education Ltd.

Figure 5.18aa

© 2018 Pearson Education Ltd.

Figure 5.18b

Figure 5.18ba

Secondary Structure

© 2018 Pearson Education Ltd.

- The **primary structure** of a protein is its sequence of amino acids
- Primary structure is like the order of letters in a long word
- Primary structure is determined by inherited genetic information

© 2018 Pearson Education Ltd.

Animation: Primary Protein Structure

© 2018 Pearson Education Ltd.

- The coils and folds of **secondary structure** result from hydrogen bonds between repeating constituents of the polypeptide backbone
- Typical secondary structures are a coil called an **α helix** and a folded structure called a **β pleated sheet**

© 2018 Pearson Education Ltd.

Animation: Secondary Protein Structure

© 2018 Pearson Education Ltd.

Video: An Idealized β Pleated Sheet Cartoon

© 2018 Pearson Education Ltd.

- **Tertiary structure**, the overall shape of a polypeptide, results from interactions between R groups, rather than interactions between backbone constituents
- These interactions include hydrogen bonds, ionic bonds, **hydrophobic interactions**, and van der Waals interactions
- Strong covalent bonds called **disulfide bridges** may reinforce the protein's structure

© 2018 Pearson Education Ltd.

Animation: Tertiary Protein Structure

© 2018 Pearson Education Ltd.

- **Quaternary structure** results when two or more polypeptide chains form one macromolecule
- Collagen is a fibrous protein consisting of three polypeptides coiled like a rope
- Hemoglobin is a globular protein consisting of four polypeptides: two α and two β subunits

© 2018 Pearson Education Ltd.

Animation: Quaternary Protein Structure

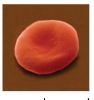

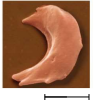

© 2018 Pearson Education Ltd.

Sickle-Cell Disease: A Change in Primary Structure

- A slight change in primary structure can affect a protein's structure and ability to function
- **Sickle-cell disease**, an inherited blood disorder, results from a single amino acid substitution in the protein hemoglobin
- The abnormal hemoglobin molecules cause the red blood cells to aggregate into chains and to deform into a sickle shape

© 2018 Pearson Education Ltd.

What Determines Protein Structure?

- In addition to primary structure, physical and chemical conditions can affect structure
- Alterations in pH, salt concentration, temperature, or other environmental factors can cause a protein to unravel
- This loss of a protein's native structure is called **denaturation**
- A denatured protein is biologically inactive

© 2018 Pearson Education Ltd.

Figure 5.20

© 2018 Pearson Education Ltd.

Protein Folding in the Cell

- It is hard to predict a protein's structure from its primary structure
- Most proteins probably go through several stages on their way to a stable structure
- Diseases such as Alzheimer's, Parkinson's, and mad cow disease are associated with misfolded proteins

© 2018 Pearson Education Ltd.

- Scientists use **X-ray crystallography** to determine a protein's structure
- Another method is nuclear magnetic resonance (NMR) spectroscopy, which does not require protein crystallization
- Bioinformatics is another approach to prediction of protein structure from amino acid sequences

© 2018 Pearson Education Ltd.

Figure 5.21

© 2018 Pearson Education Ltd.

MA1 Concept 5.5: Nucleic acids store, transmit, and help express hereditary information

- The amino acid sequence of a polypeptide is programmed by a unit of inheritance called a **gene**
- Genes consist of DNA, a **nucleic acid** made of monomers called nucleotides

© 2018 Pearson Education Ltd.

Slide 144

MA1

Monday 6Jul2020

Mamoon Al-Rshaidat, 7/6/2020

The Roles of Nucleic Acids

- There are two types of nucleic acids
 - Deoxyribonucleic acid (DNA)
 - Ribonucleic acid (RNA)
- DNA provides directions for its own replication
- DNA directs synthesis of messenger RNA (mRNA) and, through mRNA, controls protein synthesis
- This process is called **gene expression**

© 2018 Pearson Education Ltd.

Figure 5.22_1

© 2018 Pearson Education Ltd.

Figure 5.22_2

© 2018 Pearson Education Ltd.

Figure 5.22_3

© 2018 Pearson Education Ltd.

- Each gene along a DNA molecule directs synthesis of a messenger RNA (mRNA)
- The mRNA molecule interacts with the cell's protein-synthesizing machinery to direct production of a polypeptide
- The flow of genetic information can be summarized as DNA → RNA → protein

© 2018 Pearson Education Ltd.

The Components of Nucleic Acids

- Nucleic acids are polymers called **polynucleotides**
- Each polynucleotide is made of monomers called **nucleotides**
- Each nucleotide consists of a nitrogenous base, a pentose sugar, and one or more phosphate groups
- The portion of a nucleotide without the phosphate group is called a nucleoside

© 2018 Pearson Education Ltd.

- Nucleoside = nitrogenous base + sugar
 - There are two families of nitrogenous bases
 - **Pyrimidines** (cytosine, thymine, and uracil) have a single six-membered ring
 - **Purines** (adenine and guanine) have a six-membered ring fused to a five-membered ring
 - In DNA, the sugar is **deoxyribose**; in RNA, the sugar is **ribose**
 - Nucleotide = nucleoside + phosphate group
- © 2018 Pearson Education Ltd.

Nucleotide Polymers

- Nucleotides are linked together by a phosphodiester linkage to build a polynucleotide
- A phosphodiester linkage consists of a phosphate group that links the sugars of two nucleotides
- These links create a backbone of sugar-phosphate units with nitrogenous bases as appendages
- The sequence of bases along a DNA or mRNA polymer is unique for each gene

© 2018 Pearson Education Ltd.

The Structures of DNA and RNA Molecules

- DNA molecules have two polynucleotides spiraling around an imaginary axis, forming a **double helix**
- The backbones run in opposite 5' → 3' directions from each other, an arrangement referred to as **antiparallel**
- One DNA molecule includes many genes

© 2018 Pearson Education Ltd.

- Only certain bases in DNA pair up and form hydrogen bonds:
 - adenine (A) always with thymine (T)
 - guanine (G) always with cytosine (C)
- This is called **complementary base pairing**
- This feature of DNA structure makes it possible to generate two identical copies of each DNA molecule in a cell preparing to divide

© 2018 Pearson Education Ltd.

- **RNA**, in contrast to DNA, is single-stranded
- Complementary pairing can also occur between two RNA molecules or between parts of the same molecule
- In RNA, thymine is replaced by uracil (U), so A and U pair
- While DNA always exists as a double helix, RNA molecules are more variable in form
