Waleed Darawad

Course information

- Recommended textbooks
 - Marks' Basic Medical Biochemistry: A Clinical Approach 5th Edition, by Michael Lieberman (Author), Alisa Peet MD (Author), 2018
 - Biochemistry 8th edition by Mary Campbell (Author) and Shawn Farrell (Author)
- Online:
<https://themedicalbiochemistrypage.org/>
- Instructors
 - Prof. Mamoun Ahram
 - Dr. Diala Abu Hassan

Outline

- Introduction
- Acids and bases, pH, and buffers
- Macromolecules
 - Carbohydrates, lipids, and amino acids, peptides, and proteins
- Protein structure-function relationship
 - part I: fibrous proteins: collagen, elastin, and keratins
 - part II: globular proteins (plasma proteins, myoglobin, hemoglobin, and immunoglobulins)
 - part III: Regulation of hemoglobin
- Enzymes
 - structural features and classification, kinetics, mechanisms of regulation, cofactors
- Protein purification and analysis

Biochemistry & Chemical Composition of Living Organisms

Biochemistry = understanding life

such as sugars, proteins, and fats.

- Know the chemical structures of **biological molecules**
- Understand the biological function of these molecules
- Understand the interaction and organization of different molecules, **such as collagen or the constituents of the plasma membrane**, within individual cells and whole biological systems
- Understand **bioenergetics** (the study of energy flow in cells)

The structure of a biological molecule is intimately linked to its function.

For example, regarding enzymes (which stimulate reactions), each enzyme has a structure that is best suitable to help it perform its biological function.

(1) Usage and (2) Transfer of energy

Biochemistry in medicine:

- *explains all disciplines*
- *diagnose and monitor diseases*
- *design drugs (new antibiotics, chemotherapy agents)*
- *understand the molecular bases of diseases*

e.g., eating, digestion, absorption, transporting via blood, supplying cells, specific reactions inside the cell, etc....

Biochemistry, unlike anatomy or pathology, is not essential for normal physicians, but is important for elite ones!
Biochemistry is the molecular basis of diseases and is essential for developing new treatments and drugs.

Chemical elements in living creatures

- The human body is composed mainly of about 30 elements.
- Four primary elements: **carbon, hydrogen, oxygen, and nitrogen** (96.5% of an organism's weight)
- Then, calcium and phosphorus (that's 98.5%).
- Others exist in trace amounts but are essential, elements (mostly metals). **Iodine is important for the function of the thyroid gland.**

Periodic table of elements showing color-coded categories:

- Yellow:** Bulk biological elements (H, He, Li, Be, Na, Mg, K, Ca, Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ga, Ge, As, Se, Br, Kr, Rb, Sr, Y, Zr, Nb, Mo, Tc, Ru, Rh, Pd, Ag, Cd, In, Sn, Sb, Te, I, Xe, Cs, Ba, La-Lu, Hf, Ta, W, Re, Os, Ir, Pt, Au, Hg, Tl, Pb, Bi, Po, At, Rn, Fr, Ra, Ac, Th, Pa, U)
- Green:** Trace elements believed to be essential for bacteria, plants or animals (B, C, N, O, F, Ne, Al, Si, P, S, Cl, Ar, K, Ca, Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ga, Ge, As, Se, Br, Kr, Rb, Sr, Y, Zr, Nb, Mo, Tc, Ru, Rh, Pd, Ag, Cd, In, Sn, Sb, Te, I, Xe, Cs, Ba, La-Lu, Hf, Ta, W, Re, Os, Ir, Pt, Au, Hg, Tl, Pb, Bi, Po, At, Rn, Fr, Ra, Ac, Th, Pa, U)
- Red:** Possibly essential trace elements for some species (K, Ca, Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ga, Ge, As, Se, Br, Kr, Rb, Sr, Y, Zr, Nb, Mo, Tc, Ru, Rh, Pd, Ag, Cd, In, Sn, Sb, Te, I, Xe, Cs, Ba, La-Lu, Hf, Ta, W, Re, Os, Ir, Pt, Au, Hg, Tl, Pb, Bi, Po, At, Rn, Fr, Ra, Ac, Th, Pa, U)

Bulk biological elements
 Trace elements believed to be essential for bacteria, plants or animals
 Possibly essential trace elements for some species

Take a look on those tables

TABLE 2.1 Elements of the Human Body			
Name		Symbol	Percentage of Body Weight
Major Elements (Total 98.5%)			
Oxygen		O	65.0
Carbon		C	18.0
Hydrogen		H	10.0
Nitrogen		N	3.0
Calcium		Ca	1.5
Phosphorus		P	1.0
Lesser Elements (Total 0.8%)			
Sulfur		S	0.25
Potassium		K	0.20
Sodium		Na	0.15
Chlorine		Cl	0.15
Magnesium		Mg	0.05
Iron		Fe	0.006
Trace Elements (Total 0.7%)			
Chromium	Cr	Molybdenum	Mo
Cobalt	Co	Selenium	Se
Copper	Cu	Silicon	Si
Fluorine	F	Tin	Sn
Iodine	I	Vanadium	V
Manganese	Mn	Zinc	Zn

Important terms

Electronegativity is the ability of an atom to attract electrons to itself. **Oxygen and nitrogen**, for example, have very high, **carbon** has intermediate, and **hydrogen** has weak electronegativity.

- Electronegativity
- Covalent bonds are made by sharing valence electrons
 - Polar (e.g., O-H) vs. non-polar covalent bonds (e.g., C-C)
 - Electrons “spend more time” near the nucleus of the atom with the highest electronegativity
 - Because electrons “spend more time” near the atom with the higher electronegativity, this atom acquires a partial negative charge, and the other atom, which has a lower electronegativity, acquires a partial positive charge.
- Single vs. multiple: Single, double, or triple bonds

Covalent Bonds:
Molecules

Neutral

Partial Charges

Ionic Bonds:
Ionic Compounds

Full “Real” charges

Ionic bonds are generally stronger than covalent bonds due to the full transfer of electrons in ionic bonds. However, ionic bonds (like other electrostatic interactions) are destabilized in the presence of a polar solvent such as water. This is what the doctor meant when he said that ionic bonds are weaker (he meant in aqueous solution which is the norm).

Non-covalent Interactions *between molecules*; not real bonds. They are more important.

1. Electrostatic interactions: Dr. Mamoun said: between (+,-) “real” charges and that no Q in exam will be tricky about it.
Dr. Diala and the book said: between (+,-) “real”-“real”, “real”-partial, or partial-partial.

2. Hydrogen bonds (donor and acceptor), between (+,-) partial charges
e.g., in HCl, between H (partial +) and Cl (partial -) in 2 different molecules
Donor (must have hydrogen) Acceptor (electronegative)

3. Van der Waals interactions (2 types; see image on right)

Occurs due to electrons getting momentarily unevenly distributed in nonpolar molecules between the atoms creating partial charges (induced dipole) which are always changing → this is called London dispersion forces.

One is not enough, but collectively, they can make for stable strong interaction between large molecules such as proteins stabilizing a specific structure.

The one above is mainly what is meant by VDW forces; dipole-dipole also counts.

4. Hydrophobic interactions

Occurs between nonpolar covalent molecules in aqueous solution due to forming of hydrogen bonds between H₂O molecules excluding nonpolar ones.

- Hydrophilic (polar) attracting water is energy favorable
- Hydrophobic (nonpolar) attracting water is energy unfavorable
- Nucleophile (electron-rich) and electrophile (electron-poor)

Van der Waals Forces

Atoms are polarized and attract one another

Examples of Van der Waals Forces

1. London dispersion forces :
Chlorine (Cl₂)

2. Dipole-dipole interactions :
Hydrogen chloride (HCl)

Important properties of covalent bonds

- **Bond strength** (amount of energy that must be supplied to break a bond)
- **Bond length**: the distance between two nuclei
- **Bond orientation**: bond angles determining the overall geometry of atoms **in space (3D not 2D)**
- The three-dimensional structures of molecules are specified by the bond angles and bond lengths for each covalent linkage.

A carbon-carbon bond is considered a strong bond because it needs a high amount of energy to be broken.

For a given pair of atoms,
The **single bond** is the weakest and longest while
the **triple bond** is the strongest and shortest.
The **double bond** is in between.

Polarity of covalent bonds and molecules

- Covalent bonds in which the electrons are shared unequally in this way are known as polar covalent bonds. The bonds are known as “dipoles”.
 - Oxygen and nitrogen atoms are electronegative
 - Oxygen and hydrogen
 - Nitrogen and hydrogen
 - Not carbon and hydrogen

We can decide if a molecule is polar or not by trying to divide it by an imaginary line.

If there is a line which divides it into a part with net partial (+) charge and another part with a net partial (-) charge, the molecule is **polar**. Otherwise, it is **nonpolar**.

Both water and CO_2 contain polar bonds, but only water is a polar molecule.
The 2 $\text{C}=\text{O}$ bonds cancel out in CO_2 .

In a water molecule, an O atom is covalently bonded to 2 H atoms. Since the electronegativity of O is greater than that of H, each O-H bond is polar with O carrying a partial (-) charge and the 2 H each carrying a partial (+) charge. Since the geometry of the water molecule is asymmetric, the overall molecule is polar because the 2 polar bonds do not cancel each other.

What are non-covalent interactions?

- They are reversible and relatively weak.

Electrostatic interactions (charge-charge interactions):

- They are formed between two charged particles.
- These forces are quite strong in the absence of water.

van der Waals interactions

Unequal distribution of electronic charge around an atom changes with time.

The strength of the attraction is affected by distance.

Hydrophobic interactions

- They determine the whole structure of molecules (as we will see later).
- Self-association of nonpolar compounds in an aqueous environment
- Minimize unfavorable interactions between nonpolar groups and water

When nonpolar (hydrophobic) molecules are in aqueous solution, they come close together because they share the trait of “hydrophobicity”.

They prefer the interaction with another similar nonpolar molecule over the interaction with water, which is polar.

Properties of noncovalent interactions

- Reversible (at any moment, it can be broken and another one formed)
- Relatively weak

Electrostatic interactions **in aqueous solution** are considerably less stable than covalent bonds due to the competition of water molecules which try to form a hydration shell around each charged particle, separating them from each other. Covalent bonds do not exhibit such phenomenon and are thus more stable.

- Molecules interact and bind specifically Interactions between charged particles are not random but are governed by many factors.
- Noncovalent forces (attraction and repulsion) significantly contribute to the structure, stability, and functional competence of macromolecules in living cells.
- Can be either attractive or repulsive The structure forms based on that (+,+ or -,-) repels each other and that (+,-) attracts each other.
- Involve interactions both within the biomolecule and between it and the water of the surrounding environment

Carbon

The road to diversity and stability

Carbon → Diversity → Life

Properties of carbon (1)

- It can form four bonds, which can be single, double, or triple bonds.
- Each bond is very stable.
 - Strength of bonds:
 - triple > double > single
- They link C atoms together in chains and rings.
 - These serve as a backbones.

Both are glucose forms

Here, H and O;
different → diversity!

Properties of carbon (2)

- Carbon bonds have angles giving molecules three-dimensional structures.
Diversity here is due to different special arrangement of atoms governed by the surrounding environment (e.g., water, oil, or alcohol).
- In a carbon backbone, some carbon atoms rotate around a single covalent bond producing molecules of different shapes.
- The electronegativity of carbon is between other atoms (intermediate, polar bonds with O, and nonpolar bonds with H).
 - It can form polar and non-polar molecules.
- Pure carbon is not water soluble, but when carbon forms covalent bonds with other elements like O or N, the molecule that makes carbon compounds is soluble.

Water

Properties of water (1)

- Water is a polar molecule as a whole because of:
 - the different electronegativities between Hydrogen and oxygen
 - It is angular (**asymmetrical**).
- Water is highly cohesive.

A water molecule can form H-bonds with 4 molecules. This cohesive trait enables water to resist the gravity force in plants for example.
- Water molecules produce a network.
- Water is an excellent solvent because It is small, and it weakens electrostatic forces and hydrogen bonding between polar molecules.

Water can make electrostatic forces with opposite “real” or partial charges on solute molecules.

Note

Dipole-dipole interaction 2 opposite partial charges

A hydrogen bond is a dipole-dipole interaction between (1; donor) an electronegative atom covalently bonded to H atom and (2; acceptor) another very electronegative atom with lone pairs.

→ *The doctor here considered the H.....Cl (intermolecular) bond to be a hydrogen bond. We learned in previous classes that it works with (N, O, F), but Cl is also very electronegative and works fine as well.*

Dipole-charge interaction Partial with “real” charge

Properties of water (3)

- It is reactive because it is a nucleophile.
 - A nucleophile is an electron-rich molecule that is attracted to positively-charged or electron-deficient species (electrophiles).

The reaction above is favorable because (1) the water molecule is a nucleophile due to the presence of lone pairs (partial negative charge) on the oxygen atom and (2) the hydrogen has a partial positive charge.

This is why enzymes bind to their substrates inside the 3D structure (in the active site) such that surrounding water (reactive nucleophile) does not interfere in the catalyzed reaction.

Properties of water (4)

- Water molecules are ionized to become a positively-charged hydronium ion (or proton), and a hydroxide ion:

Water we drink is a mixture of mainly H_2O molecules and some H^+ (H_3O^+) and OH^- ions.

Note: $\text{H}_3\text{O}^+ = \text{H}^+$

For any feedback, scan the code or click on it.

Corrections from previous versions:

Versions	Slide #; Place of Error	Before Correction	After Correction
V1 → V2 (7 changes)	7 & 8	-----	Added the texts in dark red
	8; Electrostatic interactions	Only between full “real” charges	Is much broader (<i>see slide</i>)
	8; Van der Waals	Only being in induced dipoles	Has 2 types (<i>see slide</i>)
	10; The text in the top right	O → partial (+); H → partial (-)	O → partial (-); H → partial (+)
	13; Text under “relatively weak”	-----	Text rephrased
	19; The text in <i>italic</i> format	“H-Cl”	“H.....Cl (intermolecular)”
	19; Top right of the slide	-----	Added the text in purple
