

Ch. 1:

Pharmacokinetics:

Kidney Excretion:

A. Acidic drug. Pyrimethamine

→ Make urine basic

→ Use NaHCO_3 . Orally or IV

B. Basic drug. Phenobarbital

→ Make urine acidic

→ Use Ascorbic acid / Vit. C OR NH_4Cl
↳ Without citrate!

ATP-binding cassette family:

→ Efflux of drug outside cell. Less bioavailability

→ Less selective

A. P-Glycoprotein (MDR1 transporter):

* Brain

* Testes

* Intestines

* neoplastic cells (abnormal cell growth.. benign or malignant) (Metastasis = spread of cancer to other tissues)

B. MRP transporters:

* Excretion (Efflux) into urine & bile

* Used by some cancer cells to be resistant to chemotherapeutic agents

SLC families:

- Active transport via ion gradients, don't bind ATP.
- Secondary active transport
- Re-uptake of neurotransmitters
- Used by drugs

Endocytosis:

- Vitamin B12 - Intrinsic factor complex into blood stream in gut
↓
cuz large
- Iron - transferrin complex in RBCs.

Liver cirrhosis:

- Less oral drug lost via first pass effect.. blood bypass liver
- Drug toxicity

Solubility & low F:

Atenolol → too polar

Acyclovir → too non-polar

Grapefruit juice:

- Inhibits P-glycoprotein, MDR... MRP transporters. Less drug efflux
- Inhibit first pass effect
- ∴ more drug bioavailability
- CYP450 inhibitor. More active drug. (Less if prodrug)

F:

$$IV = 1 \text{ or } 100\%$$

A. Oral + complete absorption + first pass effect

$$F = 1 - ER$$

↳ drug lost in first pass effect

B. Oral + incomplete absorption + first pass effect

$$F = f(1 - ER)$$

↳ fraction absorbed

Vd =

Morphine:

→ ER = 0.67 . Oral + complete absorption

→ F = 1 - 0.67 . F = 0.33

Charcoal:

→ Used in drug overdose

→ Absorb drug & stops it from entering enterohepatic cycle.

→ More drug excretion. Reduce half-life

Vd:

$$Vd = \frac{\text{Drug in body}}{\text{Drug plasma conc}}$$

$$\frac{m}{\frac{m}{V}} = \frac{mV}{m} = V$$

$$V = \frac{m}{C}$$

Drug binding proteins:

Albumin

α_1 -acid-glycoprotein - binds to basic drugs

Clearance:

$$Cl = \frac{\text{rate of elimination}}{\text{Drug plasma conc.}}$$

note: See how factors affect Cl & know if x or \div .

Cl should always be V/t

$$k = \frac{0.693}{t_{1/2}}$$

$$Cl = k \times Vd \Rightarrow$$

$$Cl = \frac{0.693}{t_{1/2}} \times Vd$$

$$\begin{matrix} t_{1/2} \downarrow & Cl \uparrow \\ Vd \uparrow & Cl \uparrow \end{matrix} \Rightarrow Cl = \frac{x}{t_{1/2}} \times Vd \rightarrow \frac{L}{t}$$

$$Cl_R = \frac{\text{Drug conc. in urine} \times \text{Urine flow rate}}{\text{Drug plasma conc.}}$$

$$Cl_H = Q \cdot ER$$

Q = blood flow

$$ER = \text{extraction ratio} = \frac{C_i - C_o}{C_i}$$

ER < 1

C_i = Drug conc. entering liver

C_o = Drug conc. exiting liver

$$\text{First Order } V_o = \frac{[S] \times V_{max}}{[S] + k_m}$$

$$L_D = Vd \times C_{ss \text{ desired}}$$

Emergencies. When $t_{1/2}$ too long. L_D used

$$M_D = Cl \times C_{ss \text{ desired}}$$

First order elimination drugs:

- Most

Zero order / saturable elimination drugs:

→ A. P. E

* Aspirin

* Phenytoin

* Ethanol

High hepatic extraction ratio drug:

* Metabolized by liver fast, most in first pass effect.

* MLPV → Metabolism Liver Pass Very "fast"

* Morphine

MLPV

* Lidocaine

* Propranolol

* Verapamil

Ch.2

Routes

Angina pectoris:

→ Use sublingual route. Rapid onset

Lipid-soluble drugs:

→ CANT use IV. As precipitates in blood

Oily / Ethylene glycol:

→ Reservoir at site of administration in IM. Slower release

Asthma drug & Anesthetics:

→ Inhalational / Respiratory route

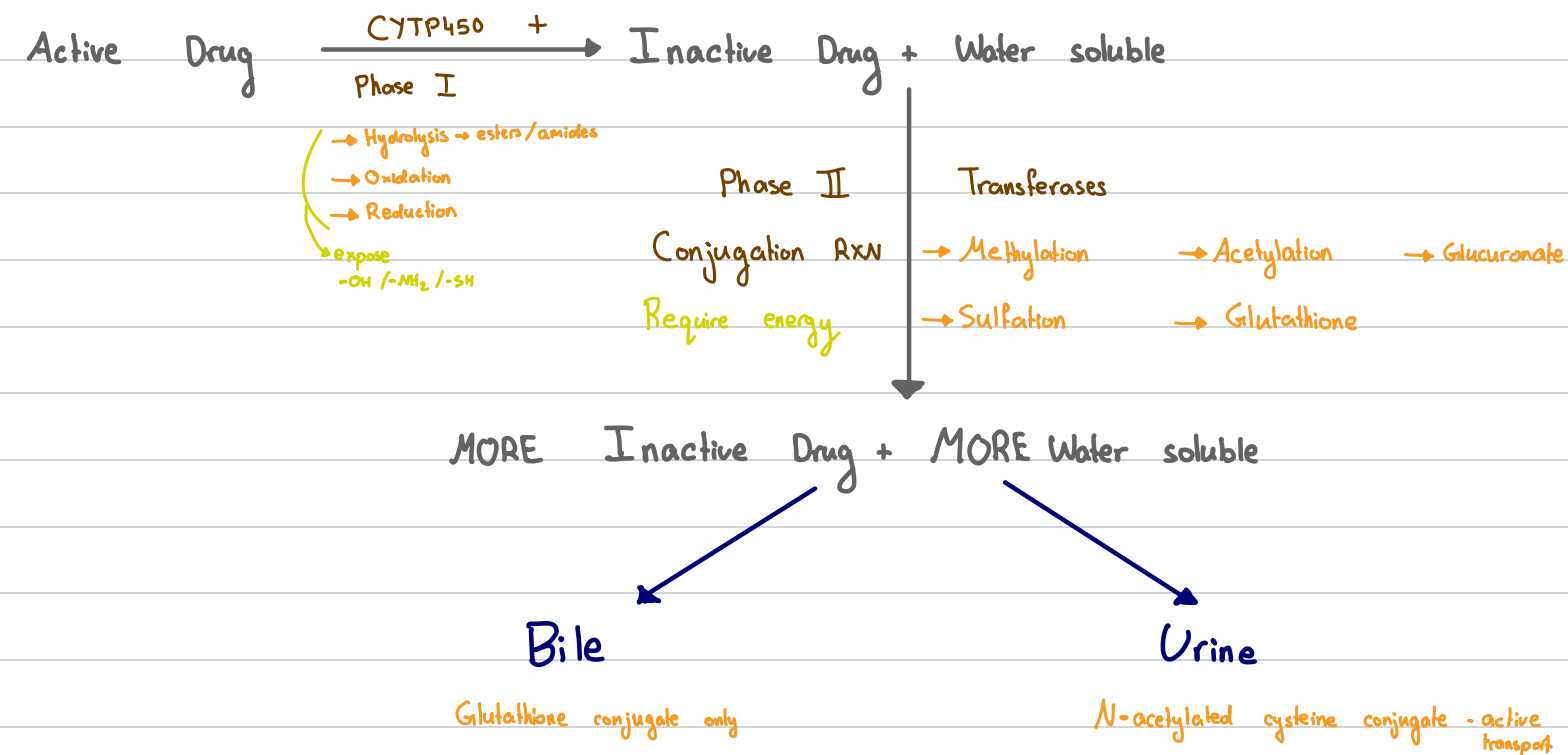

Angina:

→ Transdermal route. On skin for systemic effect.

Ch. 3

Drug Biotransformation (metabolism):

No order.

Prodrugs: (inactive to active, CYP450)

* Codeine (codeine \rightarrow morphine)

* Levodopa (levodopa \rightarrow dopamine)

* Minoxidil (activated by phase II sulfation)

Drug to toxin: (CYP450)

* Paracetamol / Acetaminophen \rightarrow N-acetyl-p-benzoquinoneimine (hepatotoxin)
 \uparrow NAPQI
 \hookrightarrow give patient N-acetyl Cysteine

* Halothane \rightarrow Free Radicals (hepatotoxin)

Important CYP450 enzyme:

> 50% of prescribed drugs

* CYP3A4

CYP450 inducers:

* Carbamazepine - autoinduction → Drug tolerance

* Barbiturates

* Phenytoin

* Rifampin

* St Johns wort

* Cruciferous vegetables

* Tobacco smoke + charcoal meat

CYP450 inhibitors:

* Erythromycin - Antibiotic. Inhibits CYP3A4

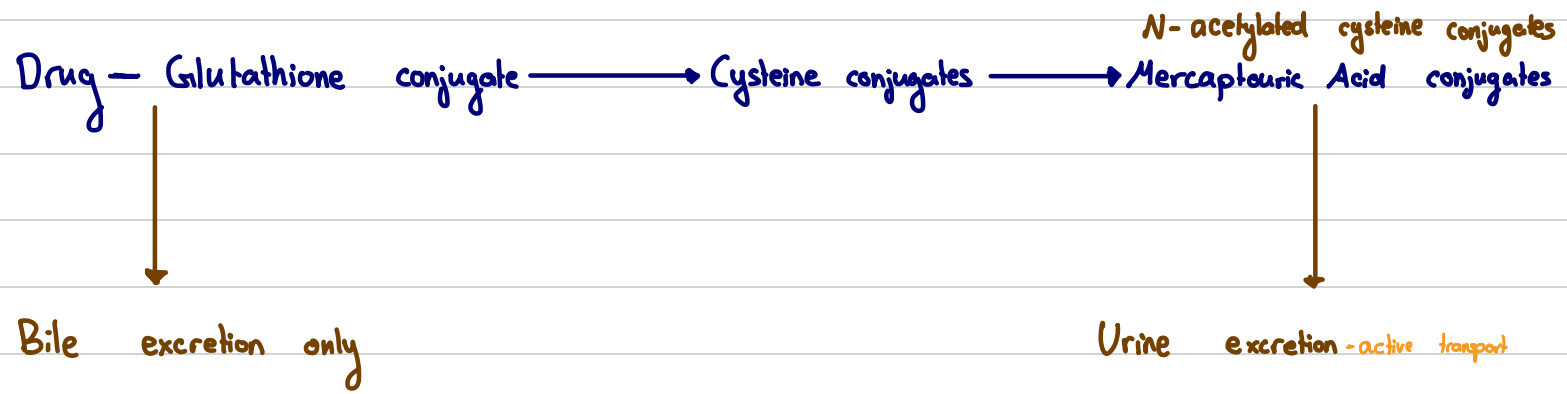

* Grapefruit furanocoumarins - Suicide inhibitor + P-glycoprotein inhibitor. Inhibit CYP3A4

Phase II points:

Type of Conjugation	Reactant w/ Drug Endogenous Reactant	Enzyme Transferase (Location)	
Glucuronidation <i>Adults more</i> <i>Most common</i>	UDP glucuronic acid	UDP glucuronosyltransferase (microsomes) UGT's	-OH -NH -SH -COOH -NHOH
Acetylation	Acetyl-CoA <i>cofactor</i>	N-Acetyltransferase (cytosol) NATs	
Glutathione conjugation	Glutathione (GSH) <i>Nucleophile</i>	GSH-S-transferase GSTs (cytosol, microsomes)	-epoxides -halogen replacement
Sulfation <i>Infants more</i>	Phosphoadenosyl phosphosulfate PAPS	Sulfotransferase (cytosol) SULT's	-OH -NH -SH -COOH -NHOH
Methylation	S-Adenosylmethionine SAMs	Transmethylases (cytosol) MTs	-N -O -S

together

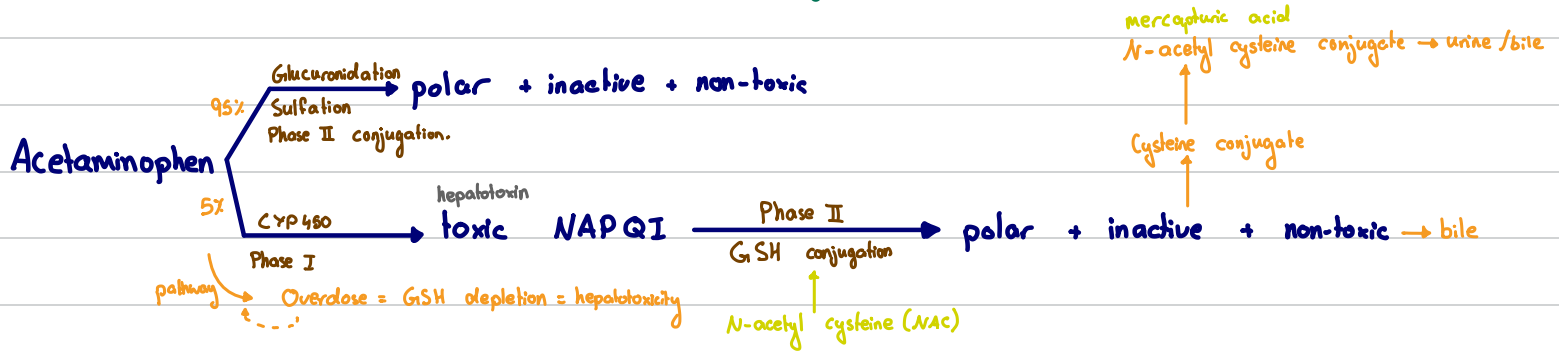

Glutathione conjugated drug excretion:

Drugs that get more active / more toxic with phase II metabolism:

- A. Morphine $\xrightarrow{\text{glucuronidation}}$ Morphine-6-glucuronide ^{more potent.}
- B. Non-steroidal anti-inflammatory drug Acyl glucuronidation. UGTs & UDP-glucuronic acid
- C. Isoniazid N-acetylation. NATs & acetyl CoA.
- D. N-hydroxyacetylaminoflourine β -sulfation. SULTs & PAPs
don't be fooled.
- E. Inactive prodrug minoxidil Sulfation. SULTs & PAPs

Acetaminophen / Paracetamol metabolism & toxicity:

Overdose: Within 8-16 hrs. Administer N-acetyl cysteine to replenish GSH & drive GSH conjugation
 (not GSH cuz cant cross membrane) \downarrow eliminate toxic NAPQI

Pharmacodynamics 1:

Receptors:

- * GABA - ion channel receptor new
- * nicotinic - ion channel receptor
- * Muscarinic - G-protein coupled receptor
- * adrenergic - G-protein coupled receptor α_1 α_2 β_1 β_2 β_3
- * Opioid - G-protein coupled receptor new
- * Insulin - Enzyme linked, RTK
- * Steroid - Intracellular receptor

Therapeutic Index: Toxic Dose : Therapeutic Dose

↑
antibiotic
Penicillin: Safe drug. Wide TI. Big gap between toxic & safe dose

Warfarin: Narrow safety margin. Narrow TI. Small gap between toxic & safe dose
↓
anti-coagulant

Beta blockers:

- * Beta adrenergic antagonist
- * Beta receptors on heart less activated. Slower heart rate.
- * Antihypertensive. Decrease blood pressure

Warfarin:

- * Anticoagulant
- * Vit.K helps in blood clotting. Warfarin inhibits Vit. k
- * Vit.K antagonist

Insulin:

- * Muscle & Liver cells increased glucose uptake

Pharmacodynamics 2:

Agonists:

A. Adrenaline / Epinephrine:

- * Adrenergic receptor agonist

B. Morphine:

- * Opioid GPCR agonist
- * CNS depressant
- * Risk of respiratory depression. Increased risk if coupled with antihistamines

Partial Agonist:

A. Buprenorphine:

- * Opioid GPCR partial agonist.
- * Weaker submaximal response ∴ Less risk of respiratory depression
- * No full agonist - Buprenorphine acts as agonist
- * Full agonist present - Buprenorphine acts as a (competitive) antagonist

Antagonists:

A. Naloxone:

- * Opioid GPCR antagonist
- * Blocks morphine analgesic ^{→ pain relief} & respiratory ^{→ Depressant} effects
- * Reverses opioid overdose
- * Given to rehab patients ~ heroin ■

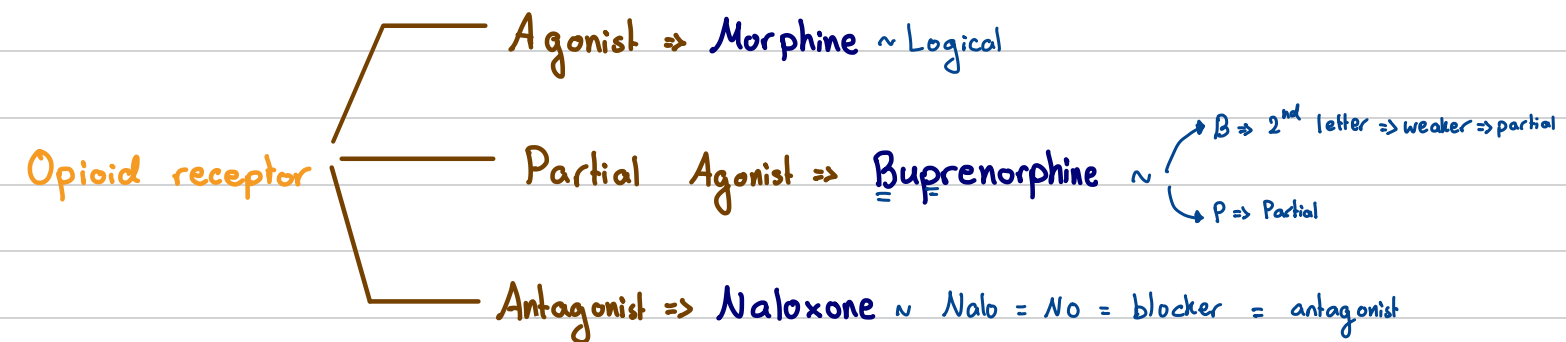

B. Beta blocker:

- * Adrenergic β antagonist of heart
- * Antihypertensive
- * End with -lol

C. Warfarin:

- * Vit. K antagonist. Anticoagulant.

Opioid Receptor memo tips:

Grapefruit Juice:

- * Inhibit P-glycoprotein - less drug efflux
- * Inhibit first pass effect - less metabolism. More bioavailability
- * Inhibit (suicide) \rightarrow CYP3A4 - less metabolism. More bioavailability

Additive $1 + 1 = 2$ Aspirin & Warfarin

Synergic $1 + 1 \gg 2$

Potentiation Increase effect of other without having effect

Antagonistic $1 + 1 < 2$ Naloxone & Morphine

Warfarin + Aspirin:

Warfarin - *Vit.K antagonist. Anticoagulant.

Aspirin - Blocks COX, less thromboxane A₂. NSAID. Less blood coagulation. More A.A directed towards PGI₂ / Prostacyclins, blood coagulation inhibited

Additive effects. 1 + 1 = 2

Alcohol + Benzodiazepines / Diazepam

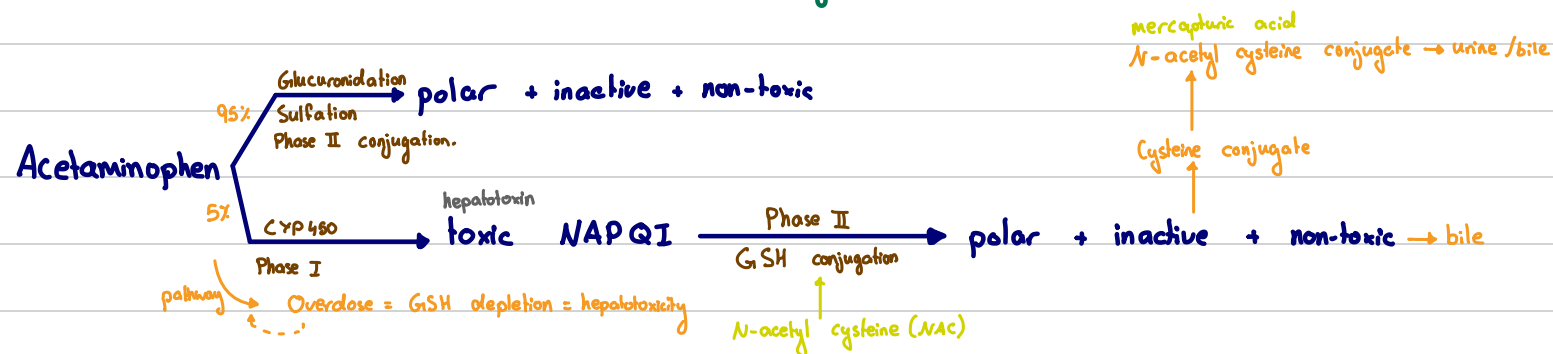

Both are CNS depressants.

Sedative effects (GABA)

Respiratory Depression !!

Synergic effects. 1 + 1 > 2

Acetaminophen / Paracetamol metabolism & toxicity:

Overdose: Within 8-16 hrs. Administer N-acetyl cysteine to replenish GSH & drive GSH conjugation
↓
eliminate toxic NAPQI

(not GSH cuz cant cross membrane)

Acute Liver Failure
