

# Drugs Used in Genital Infections Table

Drug Class & Drugs	Mechanism of Action	Pharmacokinetics (PK) & Resistance	Clinical Uses	Adverse Effects (AEs) & Contraindications
<b>Nitroimidazoles</b>  -Metronidazole  -Tinidazole	-The nitro group is chemically reduced in <b>anaerobic bacteria and sensitive protozoans</b>  -Reactive reduction products are responsible for antimicrobial activity	<b>PK:</b>  -Can be given PO, PR, Topical & IV  -Orally absorbed readily and permeates all tissues by simple diffusion  -Peak plasma concentrations reached in 1-3 hours  -Excreted mainly in the urine  -Plasma clearance is decreased in patients with <b>impaired liver function</b>  .	<b>-Bacterial vaginosis</b>  <b>-Trichomoniasis</b>  <b>-Invasive amebiasis and Giardiasis</b>  -Anaerobic bacterial infections (intraabdominal infections, brain abscess)	<b>-Metallic, bitter taste</b> , nausea & dry mouth.  -GIT irritation (vomiting, diarrhea)  -Irritation of mucous membranes (dysuria, dark urine)  <b>-Alcohol intolerance (disulfiram-like reaction)</b>  -IV infusion may be associated with seizures and peripheral neuropathy  -Better avoided during pregnancy and lactation  <b>-Potentiates the anticoagulant effect of warfarin</b>
<b>Lincosamides</b>  -Clindamycin	<b>-Inhibits microbial protein synthesis</b> by interfering with the formation of initiation complexes and aminoacyl translocation reactions  -Binds to the <b>50S ribosomal subunit</b>	<b>PK:</b>  -Widely distributed into body fluids/tissues, bone, placenta, and breast milk, <b>except brain and CSF</b>  -Accumulates in severe	<b>-Infections of the female genital tract</b> (bacterial vaginosis, septic abortion, pelvic abscesses)  -Anaerobic infections  -Osteomyelitis and Lung	-GIT irritation (nausea, vomiting, diarrhea)  <b>-Superinfection: diarrhea &amp; pseudomembranous colitis due to Clostridium difficile</b>  -Thrombophlebitis

		<p>hepatic dysfunction</p> <p>-Metabolized in liver, excreted in bile and urine</p> <p><b>Resistance:</b></p> <p>-Mutation in the ribosomal receptor site or enzymatic inactivation</p> <p>• Resistance generally <b>confers resistance to macrolides</b></p>	<p>abscess</p> <p>-Infections resulting from fecal spillage</p>	<p>-Thrombocytopenia and neutropenia</p>
<p><b>Antiherpes Agents</b></p> <p>-Acyclovir</p>	<p>-Requires <b>3 phosphorylation steps</b> for activation (monophosphate by <b>viral thymidine kinase</b>, di- and triphosphate by host cell enzymes)</p> <p>-Acyclovir triphosphate <b>inhibits viral DNA synthesis</b> via competition with deoxy-GTP and <b>chain termination</b></p>	<p><b>PK:</b></p> <p>-Low bioavailability (15-20%), unaffected by food</p> <p>-Cleared primarily by glomerular filtration and tubular secretion</p> <p>-Half-life is ~3 hours in normal renal function, 20</p>	<p><b>-Genital herpes</b> (mainly <b>HSV-2</b>)</p> <p>-Herpes labialis</p> <p>-Herpes zoster</p> <p>-Herpes encephalitis</p> <p>-Neonatal herpes</p>	<p>-Nausea, diarrhea, headache (occasional)</p> <p>-IV administration may be associated with <b>reversible crystalline nephropathy</b>, interstitial nephritis, and <b>neurologic toxicity</b> (tremors, delirium, seizures)</p>

		hours in anuria <b>Resistance:</b> -Due to alteration of either <b>viral thymidine kinase</b> or <b>DNA polymerase</b>
